Product Description

General Information

The Square D™ Distribution Transformer is designed to supply power throughout the building. The transformer permits multiple voltages to be leveraged in the design of the system.

Advantages to designing a system with low voltage transformers:

- Distributes a voltage higher than required by the load to limit wire losses and voltage drop.
- Adds source impedance to the system, reducing common overcurrent at normal voltages.
- Mitigates harmonics through an internal magnetic circuit.
- Allows system grounding closer to the load which reduces capacitive noise.
- Utilizes multiple voltage equipment since transformers can be designed for any output voltage that is required.

Disadvantages to designing a system with low voltage distribution transformers:

- Reduces overall efficiency of the system due to internal losses within the transformer.
- Adds heat to the building if installed indoors (and in the HVAC system).

The impact on the efficiency of the system and the concerns for improvements in the market for energy consumption are why low voltage distribution transformers have been regulated through the Energy Policy and Conservation Act.

The first improvement to transformer efficiency was the development of NEMA TP1 – 1996 (updated 2002). This was a volunteer standard to increase the efficiency of transformers. The second was the 2005 Energy Act which mandated the NEMA TP1 – 2002 levels for all units manufactured after January 1, 2007. EPA2005 also authorized the Department of Energy to evaluate whether or not more stringent levels should be mandated.

The Department of Energy evaluated low voltage transformers as part of an overall Distribution Transformer analysis in 2010 and 2011. They published their advanced rule in 2012 increasing the levels slightly, but chose to increase to the maximum improvement in energy efficiency that was technologically feasible. This increase occurred after multiple comments from stake holders requesting that the levels be increased beyond the levels published in 2012. The final levels which were published in April 2013 effect all transformers manufactured after January 1, 2016. The increase in efficiency only effects three-phase units.

Square D™ Brand EX Low Voltage Distribution Transformers

Product Description

Department of Energy (DOE) Compliance

10 CFR 431 – Energy Conservation standards

431.196 (a) Low Voltage Transformers

(2) The efficiency of low voltage dry-type distribution transformers manufactured on or after January 1, 2016 shall be no less than that required for their kVA rating in the Table 1.

Table 1: Efficiency Ratings of Low Voltage Dry-Type Distribution Transformers

Single-phase ¹		Three-phase	
kVA	Efficiency (%)	kVA	Efficiency (%)
15	97.70	15	97.89
25	98.00	30	98.23
37.5	98.20	45	98.40
50	98.30	75	98.60
75	98.50	112.5	98.74
100	98.60	150	98.83
167	98.70	225	98.94
250	98.80	300	99.02
333	98.90	500	99.14
—	—	750	99.23
—	—	1000	99.28

NOTE: All efficiency values are at 35 percent of nameplate-rated load, determined according to the DOE Test Method for Measuring the Energy Consumption of Distribution Transformers under Appendix A to Subpart K of 10 CFR part 431.

¹ Single-phase ventilated transformer efficiencies remain the same as the 2007 levels. Single-phase transformers retain their design, EE prefix, and catalog numbering structure. For information on single-phase products, refer to the Energy Efficient Single Phase and Single Phase Watchdog section in Digest 177, Section 14 and to catalog no. 7400CT0601.

Low-voltage, dry-type distribution transformers with kVA ratings not appearing in Table 1 have their minimum efficiency level determined by linear interpolation of the kVA and efficiency values immediately above and below that kVA rating.

The new Type EX Energy Efficient Low Voltage Dry-Type Distribution Transformers comply with the new levels of efficiency.

Square D™ Brand EX Low Voltage Distribution Transformers

Product Features

Product Features

New Energy Efficient Transformer Family – EX

The efficiency levels set by the U.S. Department of Energy necessitated completely new transformer designs. Components used within Schneider Electric™ transformers were optimized for performance, including:

- **Coil**—Computer designed to reduce the losses with customized wire configurations used exclusively by Schneider Electric. Computer winding equipment to minimize variability during the winding process. Available as standard with aluminum conductor, but also available with copper.
- **Insulation System**—The system consists of a conductor wrap or coating, layer insulation, air gap spacing, and varnish material. The system is UL listed for a specific maximum temperature for average temperature rise, hot spot, and ambient temperature. Schneider Electric's EX family of transformers have a 428°F (220°C) insulation system, with an average temperature rise maximum of 302°F (150°C). The design also allows further reduction in conductor losses, while also offering the product with an average temperature rise of 239°F (115°C) or 176°F (80°C).

Figure 2: Insulation System

- **Core**—Transformers are designed with high grade grain oriented, non-aging silicon steel laminations with high magnetic permeability and low hysteresis and eddy current losses. The computer design program allows the design to keep the magnetic flux densities well below the saturation point. The laminations are carefully and evenly stacked in one of two core configurations: distributive gap or full step mitre. Then they are clamped together to ensure the most efficient magnetic circuit while providing a quiet quality offering of low voltage transformers.
- **Terminals**—Sized to allow the lugs to align with all corresponding Schneider Electric equipment (such as: circuit breakers, switches, panels, switchboards, and so forth). Layout separates the Primary and Secondary terminals and meet the NEC minimum bending requirements. Lugs are not shipped with the transformers to give the installer the flexibility to meet any distribution system conductors requested. All incoming terminals are sized for 125% or 250% lug landing.

NOTE: Both mechanical and compression lug kits are available from Schneider Electric.

Square D™ Brand EX Low Voltage Distribution Transformers

Product Features

- Enclosure—Two new enclosure styles: K and J. See Figure 3.
 - **Style K** units are designed with no top or rear ventilation and alcove tested with ½ in.(12.7 mm) clearance from the rear and sides. The front and rear panels are designed to attach to the cover, increasing the support strength of the tops. The base is vented and designed with a conduit entry and three locations for mounting a ground terminal bar.
 - **Style J** units are designed with no rear ventilation and alcove tested at ½ in.(12.7 mm) clearance from the rear and sides. The front and rear panels are designed to attach to the cover via a u-shaped lip, increasing the support strength of the tops. The open design of the enclosure base includes three locations for mounting a ground terminal bar.

Both enclosures have mounting holes on the side allowing for the use of a floor mounting kit, to more easily bolt the unit to the floor.

Figure 3: Style K and J Enclosure

- Nameplate—Two nameplates are supplied with each unit (see Figure 4). One on the front cover which is required by standards, the second nameplate is attached to the core and coil, providing installation information inside the unit. The second nameplate also carries a UR listing for the core and coil, allowing the enclosure to be removed and the device installed in other equipment.

Square D™ Brand EX Low Voltage Distribution Transformers

Product Features

- Testing—All designs are tested at state of the art test labs, UL certified, and part of the test program.
 - UL 1561 and NEMA ST-20 design and prototype testing are done on initial design
 - DOE product verification testing is completed yearly in compliance with 10 CFR 429
 - Routine testing is completed on 100% of all units shipped from the facilities.Testing is performed on all units shipped.
- Packaging—Shipping materials are updated to insure the new designs arrive undamaged from handling and logistics. Pallets are designed to increase clearances between units, and spacers are added underneath the box to prevent small dings in the enclosure. The enclosure design is also enhanced to prevent damage during shipments.
- Quiet Quality—All units are designed and tested to sound levels 3–6 dB below the NEMA ST-20 tables. Because each 3 dB cuts the audible sound in half, this new offering has the quietest units in the marketplace.
- Manufacturing—All units are built in two ISO registered facilities.
- Product Environmental Profile:
 - RoHS compliant
 - REACH compliant
 - Eco-Passport

Calculation of regulation on a transformer is complex, requiring information about load power factor as well as amperage. Since complete information is often lacking, a worse case calculation, as shown below, is often used to provide conservative results:

$$\text{Voltage drop (\%)} = \frac{\text{Maximum load current}}{\text{Transformer secondary full load rating}} \times \text{Impedance (\%)}$$

Square D™ Brand EX Low Voltage Distribution Transformers
Electrical Data

When voltage is applied to the input winding of a transformer there can be a brief period of inrush current until the transformer core is stabilized. Inrush lasts approximately 6 power cycles, or about 0.1 seconds. The magnitude of the inrush varies depending on when the switch closes on the power wave, so that inrush can be anywhere from zero to greater than the full load current rating of the transformer. In addition, the impedance of the supply system can influence the amount of inrush current the transformer can draw. To avoid tripping breakers, or blowing fuses on the primary side of the transformer during energizing, careful coordination of fuse sizes or breaker handle ratings and magnetic trip settings is essential. This coordination requires information about maximum possible inrush to be expected from the particular transformer in question.

Schneider Electric has taken the inrush data for our units and plotted this data on our circuit breakers' trip curves. As a result of this data, it has been determined that circuit breakers sized at either the NEC 125% or 250% levels will energize the product without tripping.

Tables 19, 20, 21, 22, and 23 on pages 31-35 permits completion of the analysis by supplying the maximum inrush times rated, but also includes the type of breaker at the NEC level listed for a quick guide to choosing the proper transformer breaker.

Figure 6: Primary and Secondary Protection

The following tables were developed by modeling the transformers in PTW software and plotting trip curves for each listed trip unit at the given amperage. Then, it was verified whether or not the device could carry the full load inrush multiplier at 0.01 seconds.

NOTE: Setting is the minimum instantaneous (INST) level for the sensor. For circuit breakers with trips allowing settings, the value is shown and the sensor is in ().

Square D™ Brand EX Low Voltage Distribution Transformers

Electrical Data

Transformer efficiency can be defined as the percentage of power out compared to the percentage of power in. A perfect zero loss transformer would have the same power in as out, and would be 100% efficient. With the implementation of EPACT2005 Final Rule 10 CFR 431 Subpart K, most low voltage transformers exceed 98% at 35% load.

For compliance with the 2005 Energy Act, manufacturers must measure and calculate the efficiency levels using the following formula:

$$\% \text{ Efficiency} = \frac{100 \times P \times VA}{(P \times VA) + \text{Core Loss} + (P^2 \times \text{Coil Loss} \times T)}$$

Where:

P = per unit load (EPACT2005 = 0.35)

T = correction factor for winding material and temperature correction (convert to 167°F [75°C])
(302°F [150°C] Rise AL = 0.8152; CU = 0.8193)

Correction factors are used because resistance losses vary by temperature and winding material. See 10 CFR 431.192 for more details on formula..

Table 11: Transformer Efficiency

Manufacturers are required to use sampling plans for Distribution Transformers under Department of Energy 10 CFR 429.47.

Manufacturers can use actual test results in accordance with 10 CFR 431.193, to certify:

- a. Basic Models
- b. kVA Groups

Manufacturers may also use Alternative Methods for Determining Efficiency for (AEDM) per 10 CFR 429.70.

Core loss (No-Load Loss): When a transformer is energized on the primary side, the laminated steel core carries a magnetic field, or flux. This magnetic field causes certain losses in the core, generating heat and dissipating real power from the primary source even when no load is on the secondary side of the transformer.

Coil Loss (Load Loss): Under load, a transformer loses energy in the form of heat within the winding conductors. That's because these conductors have a certain amount of resistance. Nearly all of the coil loss can be accounted for by the simple I^2R (current in amperes squared times resistance in ohms) formula for watts. There is a small amount of stray losses, and the sum of these and I^2R watts equal total coil loss.

These losses are typically reported by engineering in watts. Many contractors interested in air conditioning requirements of a building will request the BTU/HR (British Thermal Units per hour) equivalent, which can be determined as follows: $\text{BTU/HR} = 3.412 \times \text{Losses in Watts}$.
